National guidelines for treatment of asthma include recommendations for providing written asthma action plans (AAPs) to support patient self-management. However, AAP completion rates often remain low despite such recommendations. Proactive, clinic-based approaches to asthma management have shown promise in increasing the use and ownership of AAPs, but they involve extensive provider training and/or health care worker time commitments.

During the period 2005 to 2006, our academic health center reported low AAP completion rates (7.5%; 884 of 11,785 patients) despite existing guidelines, AAP templates, and feedback from a quality improvement team. With no formal process in place for implementing clinic practice change, we piloted a team-based approach to increase the number of patients with written AAPs at 5 community-based family medicine clinics. The clinics handled 1300 to 2500 patient visits per month with staffing levels of 8 to 17 physicians and 2 to 4 registered nurses (RNs). A clinical quality management system (CQMS, Crimson Care Registry, Ann Arbor, MI) provided reminders to the physician at the time of the office visit. The system was capable of monitoring management for patients with chronic conditions, producing lists of patients with persistent asthma, delivering evidence-based reminders for asthma management, and tracking provider-generated responses.

Methods
Our team-based approach involved CQMS reminder use and nurse engagement in AAP development to increase the number of asthma patients with written AAPs. Because merely educating physicians to provide AAPs does not necessarily lead to changes in practice, we used RNs and the CQMS. A family medicine physician, an outpatient pulmonary care RN, and a family medicine outpatient RN (both RNs are certified as asthma educators) developed a 2-hour educational program for delivery to RNs, faculty, and residents. National guidelines for patient education shaped topic selection and AAP...
template design. Physicians received a 15-minute introduction to the new AAP prompts, RN referral process, AAP templates, and educational materials. Patients met with RNs for 1 hour or less after regularly-scheduled office visits as a follow-up to physician recommendations or in response to telephone invitations made by clinic staff using CQMS-generated patient lists.

After receiving an institutional review board non-regulated determination, we reviewed Blue Cross/Blue Shield’s Physician Group Incentive Program (PGIP) and CQMS data to examine AAP response rates between June 2007 and December 2009. We analyzed data descriptively and by simple linear regression over time (PASW Statistics 18.0; SPSS/IBM, Chicago, IL).

**Results**

From 2006 to 2009, we educated 14 RNs, 30 residents, and 56 faculty. RNs wrote ~98% of the AAPs based on physician and RN reports. Inclusion criteria for persistent asthmatics in the PGIP database somewhat differed over time because of changes in the reporting criteria of our internal health system, with a total of 10,071 to 11,686 recorded per year during the study period. Physician responses to the CQMS reminders remained high, ranging from 78% (993 of 1276) in 2007 to 90% (1481 of 1647) in 2009 ($P = .121$). Responses to AAP reminders included “completed today” (26%), “ordered for upcoming visit” (9%), “did not address due to more pressing health concern at visit” (13%), “discussed/deferred” (49%), and “refused” (3%).

From June 2007 to December 2009, the total number of patients provided with written AAPs increased significantly over time at most family medicine clinics, and at a level that exceeded other primary care clinics within the health system (Figure 1). Clinic 3 served as the pilot site, and AAP rates remained highest there for the majority of the study period, only showing a slight decline in late 2009 after reaching saturation.

**Discussion**

In this study, AAP completion rates increased over time, with the largest and most rapid increases attributed to easily adopted clinical processes, as recommended by Ring et al following a systematic review of research about promoting AAP use. PGIP funding during this time was only used for development of the database and was not used for other asthma care improvement activities.

AAP completion rates rose throughout the institution, but the greatest improvements were shown in family medicine clinics that systematically implemented asthma training programs, use of clinical reminders, and enhanced RN engagement. Although our review was limited to retrospective analysis of data from a single family medicine department, the results suggest that proper RN and physician training coupled with the use of clinical reminder systems can significantly improve the number of AAPs provided to primary care patients.
Conclusion
Practices with low AAP completion rates may find a team-based approach helpful in increasing the provision of written AAPs for patients with persistent asthma.
