Physician Advice for e-Cigarette Use

Christy Kollath-Cattano, PhD, James F. Thrasher, PhD, Amira Osman, PhD, Jeannette O. Andrews, PhD, RN, and Scott M. Strayer, MD, MPH

Purpose: To determine characteristics of smokers discussing e-cigarette use with their physician and receiving recommendations from their physician to use e-cigarettes for smoking cessation.

Methods: US adult smokers who had visited a physician in the previous 12 months ($n = 2671$) were surveyed. Logistic generalized estimating equation models were used to assess the characteristics of smokers who (1) talked to a physician about e-cigarettes, and (2) received physician advice to use e-cigarettes for smoking cessation.

Results: 15% ($n = 406$) of smokers who visited a physician talked with their physician about e-cigarettes. Among those asked whether their physician recommend e-cigarettes for smoking cessation ($n = 257$), 61% responded affirmatively. Current e-cigarette users were more likely to talk to their physicians about e-cigarettes (nondaily users vs never users: OR, 2.70; 95% CI, 1.79–4.05; daily users vs never users: OR, 4.29; 95% CI, 2.34–7.84) and have their physician recommend e-cigarettes for smoking cessation (daily users vs never users: OR, 9.40; 95% CI, 2.54–34.71).

Conclusions: The majority of smokers who talk to their physician about e-cigarettes report that they received advice to use e-cigarettes to quit smoking, despite limited evidence for their efficacy. More studies are needed to better understand e-cigarette recommendations in clinical settings. (J Am Board Fam Med 2016;29:741–747.)

Keywords: Electronic Cigarettes, Physicians, Smoking, Smoking Cessation, Surveys and Questionnaires, Tobacco Products, Tobacco Use Disorder

Electronic cigarette (e-cigarette) use has increased dramatically in recent years, including among smokers using it to facilitate smoking cessation.^{1,2}

However, evidence on the effectiveness of e-cigarettes in smoking cessation is limited.^{3–5} The US Preventive Services Task Force⁶ and other regulatory and medical organizations have not found sufficient evidence to recommend their use for cessation.^{7–9}

Most physicians seem to believe that e-cigarettes are less harmful than conventional cigarettes^{10–12} and that e-cigarettes promote smoking cessation, with one-third (35%) recommending them to patients who smoke cigarettes.¹⁰ In the only study on this topic from the patient perspective, 27% of smokers ($n = 250$) reported ever talking with their physician about e-cigarettes; discussions were most prevalent among current e-cigarette users.¹³ Two thirds of those who spoke with their physician about e-cigarettes (66%; $n = 165$) reported that their physician recommended them; however, this study did not assess other correlates of physician recommendations, or whether physicians recommended e-cigarettes specifically for smoking cessation.¹³ To better characterize physician counseling about e-cigarettes, our study evaluates the charac-

Figure 1. Study flow chart.

teristics of smokers who report discussing e-cigarettes with their physician and physician recommendations to use e-cigarettes for smoking cessation.

Methods

Sample

Data were analyzed from a longitudinal survey of US adult smokers recruited from Global Market Insights (www.gmi-mr.com), which provides online panels of consumers who represent key market segments. Recruitment involved sending invitations to panel participants who were of eligible age and were known smokers, as well as from samples of the general population for which smoking status was unknown. Because of the aims of the parent project, US Latinos were oversampled to allow comparison with a Mexican sample. Eligible partici-

pants were smokers aged 18 to 64 years who smoked at least 100 cigarettes in their lifetime and at least once in the previous month.

Data were pooled across waves collected in May 2014 (n = 1420; wave 6), September 2014 (n = 1450; wave 7), and January 2015 (n = 1401; wave 8). However, a question about whether smokers received physician advice to quit using e-cigarettes was only asked in waves 7 and 8 (Figure 1). Response rates to invitation E-mails were 16% at wave 6, 4% at wave 7, and 3% at wave 8. Follow-up rates were 60% from wave 6 to wave 7, and 75% from wave 7 to wave 8. Participants lost to follow-up were replaced to maintain sample sizes at each wave. Participants were compensated from \$1.75 to \$2.50 for survey completion. The University of South Carolina's institutional review board approved the study protocol.

Measures

Talking to a Physician about e-Cigarettes

At all waves, respondents were asked whether they had visited a physician in the past 12 months. Those who did were asked, "Have you and your doctor talked about e-cigarettes?" (no = 0, yes = 1).

Physicians' Advice to Use e-Cigarettes for Smoking Cessation

In waves 7 and 8, those who reported talking to their physician about e-cigarettes were asked, "Did your doctor recommend that you use e-cigarettes to help you quit smoking regular cigarettes? (no = 0, yes = 1).

Control Variables

Standard sociodemographic (age, sex, education, annual household income, race/ethnicity) and smoking-related variables (daily smoking, number of cigarettes smoked per day, intention to quit, and attempts to quit), as well as e-cigarette use, were assessed (Table 1).

Statistical Analyses

We used 2 analytic samples, which consisted of (1) smokers who visited a physician in the past 12 months, with no missing data on study variables ($n = 2671$ observations pooled across waves 6, 7, and 8); (2) smokers who talked to their doctor about e-cigarettes and were asked whether they received advice to use them to quit ($n = 257$ observations; $n = 221$ individuals at waves 7 and 8, when the question on advice was asked) (Figure 1).

Using data from all waves ($n = 2671$ observations), bivariate and multivariate logistic generalized estimating equation models were estimated, regressing talking to a physician about e-cigarettes on study variables (Table 2). Using data from waves 7 and 8 ($n = 257$ observations), logistic generalized estimating equation models were estimated, regressing receipt of advice to use e-cigarettes to quit on study variables (Table 2). Analyses were weighted for sex, age, and educational profiles of the general population of US smokers based on estimates from the 2012 National Health Interview Survey.¹⁴ We determined the statistical significance of associations using a Bonferroni-adjusted α level of 0.0042 per test (0.05/12 predictors). All analyses were conducted using Stata software version 13 (StataCorp, College Station, TX).

Results

Of all participants who visited a physician in the previous 12 months (sample 1), 15% reported talking to their physician about e-cigarettes, and 61% of participants asked about doctor recommendations (sample 2) reported that their physician recommended using e-cigarettes to quit regular cigarettes (Table 1). Compared with smokers who never used e-cigarettes, current e-cigarette users were more likely to talk with their physician about e-cigarettes (nondaily users: odds ratio [OR], 2.70; 95% confidence interval [CI], 1.79–4.05; daily users: OR, 4.29; 95% CI, 2.34–7.84). Current daily e-cigarette users were also more likely to receive advice to use e-cigarettes for cessation (OR, 9.40; 95% CI, 2.54–34.71) compared with those who never used e-cigarettes. Smokers who were male or who had recently attempted to quit were more likely than their counterparts to talk to a physician about e-cigarettes (Table 2).

Discussion

Physician advice on smoking cessation is essential and recommended to decrease smoking, as >70% of smokers visit a physician annually.¹⁵ Recently issued US Preventive Services Task Force recommendations on smoking cessation state that clinicians should use only approved medications and behavioral interventions for smoking cessation (level A recommendation) and cite insufficient evidence for the benefit of e-cigarettes.⁶ A recent Cochrane review of e-cigarettes also concluded that the evidence was weak for using these devices for smoking cessation.⁵

Nevertheless, most smokers who spoke with physicians about e-cigarettes reported that their physicians recommended e-cigarettes for smoking cessation (61%). The 15% estimate of the prevalence of e-cigarette discussions is lower than previous estimates (27%)¹³; however, this is likely explained by our study asking about the past 12 months, whereas the other study had no time frame. Greater intensity of e-cigarette use was associated with both talking about e-cigarettes and receiving advice to use e-cigarettes for smoking cessation, perhaps indicating that physicians are working with patient preferences and perceive using e-cigarettes as being safer than continuing to

OR, odds ratio; CI, confidence interval.

smoke regular cigarettes. Those who made a recent attempt to quit were also more likely to have talked to their physician about e-cigarettes, suggesting they may have been either considering or already using e-cigarettes for cessation when they spoke with their physician. Women were less likely than men to talk to their physician about e-cigarettes, which may reflect lower e-cigarette use among women.^{16,17} No other sociodemographic variables were associated with study outcomes.

Future research should assess sex differences in how e-cigarettes are addressed during clinical encounters. More research is needed to determine whether these sex differences persist in other samples of smokers. In addition, future studies should explore characteristics of physicians who talk to their patients about e-cigarettes for smoking cessation, the content of these conversations, and subsequent smoking cessation outcomes.

The primary limitation of the study is that the study sample comes from an unknown sampling frame, limiting the generalizability of these results. In addition, our sample replenishment strategy might have introduced some bias; however, we conducted a sensitivity analysis with propensity scores, and the results show no evidence of bias. Moreover, the original and replenishment samples were purposefully assembled to be representative of key marketing segments, even though the patients in the sample had more education than the general population of smokers in the United States. Internet access partly explains this potential sampling bias; as of 2013, however, 74% of the US population had household Internet access, thus limiting this bias.¹⁸ To address this concern, analyses were weighted to resemble the general population of US smokers. Future research should assess whether our results are similar among populations with lower socioeconomic status. The study design limited our ability to determine physician influences; therefore future research should assess smokers' perceptions and use of e-cigarettes before and after discussions with physicians. Smokers' self-reports about clinical encounters may not be accurate, although the direction of biases in our results is unclear. Smokers may have mistakenly believed their physician recommended e-cigarettes for smoking cessation; however, most physicians self-report recommending e-cigarettes for smoking cessation in other research.¹⁰ In addition, we did not assess who initiated discussions of e-cigarettes or whether

physicians recommended evidence-based cessation methods over e-cigarettes. The only study of physician screening for e-cigarettes found that only 24% of obstetrician-gynecologists reported always asking patients about e-cigarette use.¹⁹ Research on physician screening and physician-patient dialogue is needed to determine how e-cigarettes are discussed in the context of alternative cessation methods and how patients are advised to use e-cigarettes.

Conclusion

Despite these limitations, this is the first study to describe discussions of e-cigarettes between physicians and smokers. With the widespread availability, marketing, and use of e-cigarettes, it is increasingly important to understand the role of e-cigarettes in smoking cessation counseling. Our study provides additional evidence that most smokers who speak with their physicians about e-cigarettes receive advice to use them for smoking cessation. These smokers tend to be male and current e-cigarette users. This highlights the need for further research on the efficacy, safety, and use of e-cigarettes among smokers, and on how physicians should talk to their patients about e-cigarettes.
