

COMMENTARY

Family Medicine and the “New” Opioid Epidemic

Mark S. Johnson, MD, MPH

(J Am Board Fam Med 2020;33:1–3.)

The opioid crisis is America’s Ebola. Often fatal, complicated, with multiple ramifications that go beyond just medicine to the core of our culture. Clinicians’ response to pharma promotions and pain as the fifth vital sign is part of that culture. The complicity of pharma is being adjudicated in the courts. Solutions to this problem have been evolving quickly as a new urgency has erupted in response to the magnitude of the death rates. And as we explore solutions to this “new” epidemic, we see that solutions for one thing can cause problems for another. In this example, we find that those who believe that they need and thus should have access to chronic opioids are having trouble getting them. We also find that many of these patients have not had appropriate trials to reduce dosages or try alternate modes of therapy. Furthermore, the current climate has increased the fear that clinicians feel when “confronted” by a patient in pain. We need research to create the evidence that will yield best practices.

Family Medicine Care

The involvement of family physicians in the care of these patients has escalated by necessity. Practitioners in small towns around the country began to see their patients die. They had no idea that John or Jill was addicted. Many did not know that the prevalence of opioids was increasing exponentially in their communities. This special issue of the *Journal of American Board of Family Medicine (JABFM)* provides a glimpse into this complex problem. A major focus of care to those with opioid-use disorder

(OUD) is medication-assisted therapy (MAT). The role of family medicine in MAT is evolving. Several articles in this issue describe these roles.

Peterson et al¹ used the unique database of those taking the American Board of Family Medicine (ABFM) certification examination to elucidate important variables with a 100% response rate. They found that 5.9% of family physicians reported prescribing buprenorphine. Family physicians who worked in a Federally Qualified Health Center (FQHC), those in solo practice, or who had a mental health professional working with them were more likely to prescribe. In a policy brief, Peterson and his team² report that graduating residents and early career family physicians are leading the growth of new prescribers, so a bigger effort will be required from midcareer and older family physicians if we are going to substantially increase those ready to prescribe. This is more important when one considers that many of those who do get the waiver will never actually prescribe, because of real and perceived barriers. Abraham et al,³ using Medicare data, found that while family physicians and internists were the main prescribers of buprenorphine, only 2.7% and 2.0% were prescribing, respectively. Factors considered to increase likelihood of prescribing were male gender, northeast location, DO degree, US undergraduate training, more years in practice, and more dual eligible patients.

A number of articles examine facets of opioid prescribing. Sokol’s team⁴ used 2 models of change to promote practice improvement for care to both those with OUD and those who are prescribed opioids. Articles by van Eeghen et al⁵ and Breeden et al⁶ use best practices to improve adherence to opioid prescribing guidelines. The article by Raad et al⁷ shows that the prescribing of opioids for low-back pain declined from 2011 to 2016. However, there were still large differences in prescribing

Funding: none.

Conflict of interest: The author is an Editorial Board member of the *JABFM*.

ing by state. Jerant et al⁸ looked at patient satisfaction related to opioids and found that 6 or more opioid prescriptions per year was associated with higher patient satisfaction. DiIulio et al⁹ used qualitative methods to examine reasons for changing existing chronic pain management plans.

Magnan et al¹⁰ looked at patient satisfaction related to having a denial from the doctor. Although the denial of pain medication was one of the reasons considered, they did not offer separate data to understand this possible contributing factor. However, they did point out the importance of continuity. Two articles discuss nonopioid substances. Redinger et al¹¹ propose an ethical framework for medicinal marijuana that helps physicians make decisions based on their beliefs within the current legal restraints. Loskutova et al¹² conducted a survey of family physicians and college health professionals to determine practice patterns regarding stimulants and the growing concerns about stimulant diversion.

Other important topics are covered in this issue as well. The team lead by Purkable¹³ conducted an intervention to promote discussions of quality of life goals. The associations between education level, depression care, and shared decision making is explored in the article by Brodney et al.¹⁴ Crego et al¹⁵ examined the relationship between comanagement and hydroxyurea utilization in sickle-cell patients covered by Medicaid. A qualitative analysis by Moerenhout et al¹⁶ explored ethical questions posed by shared electronic medical records. Johansen et al¹⁷ used the Medical Expenditure Panel Survey (MEPS) database to determine the frequency and type of medication combinations used for hypertension.

Need for Future Research

Those of us who have been practicing in urban centers know that this “epidemic” is not new. It may be different because now those affected are more likely to be white and young. It is also different because those so afflicted are more likely to be seen as ill instead of having a moral failing. For our response to the current need to be successful, it will take more clinician person power and more research. This research need cries out for interdisciplinary collaborations of all types. We need more research on the genomic susceptibility and the genomics of treatment.¹⁸ We need research with

communication experts and anthropologists about the optimizing the messaging from clinicians to achieve the desired outcomes. We need research with social workers and other providers to determine the contribution of case management models to promote adherence. Research is needed with behavioral scientists with particular attention to the fact the many of our OUD patients also have comorbid psychiatric diagnoses. And as suggested by the Farrar article,¹⁹ we need more economic analyses to determine feasibility and outcomes from different care designs.

Need for Qualified Family Physicians

A major problem is a shortage of family physicians who can act as clinical mentors to those who have completed waiver training. Increasing the number of family physicians who complete addiction medicine fellowships (and increasing the number of departments who sponsor them) will improve this situation. Another strategy is using Extension for Community Healthcare Outcomes (ECHO) methods for telementoring.²⁰ Finally, advocacy deserves to be mentioned regarding the emergence of OUD as a rising public health problem. We must inoculate our nation to protect our citizens from the spread of addiction and reduce the social conditions that predispose us to OUD and that result from OUD. Family physicians could and should advocate to remove barriers to care with government, insurance companies, and law enforcement.
