

BRIEF REPORT

A Financial Model for Team-Based Opioid Use Disorder Treatment

Mackenzie Farrar, PharmD, Zach White, LCSW, LCAS, Stephen Hulkower, MD, E. Blake Fagan, MD, and Courtenay Gilmore Wilson, PharmD, BCACP, CPP

Introduction: Opioid use disorder (OUD) affects 2 million Americans, yet many patients do not receive treatment. Lack of team-based care is a common barrier for office-based opioid treatment (OBOT). In 2015, we started OBOT in a family medicine practice. Based on our experiences, we developed a financial model for hiring a team member to provide nonbillable OBOT services through revenue from increased patient volume.

Methods: We completed a retrospective chart review from July 2015 to December 2016 to determine the average difference in medical visits per patient per month pre-OBOT versus post-OBOT. Secondary outcomes were the percentage of visits coded as a Level 3, Level 4, and Level 5, and the percentage of patients with Medicaid, private insurance, or self pay. With this information, we extrapolated to build a financial model to hire a team member to support OBOT.

Results: Twenty-three patients received OBOT during the study period. There was a net increase of 1.93 visits per patient per month ($P < .001$). Fourteen patients were insured by Medicaid, 7 had private insurance, and 2 were self pay. Twenty-three percent of OBOT visits were Level 3, 69% were Level 4, and 8% were Level 5. Assuming all visits were reimbursed by Medicaid and accounting for 20% cost of business, treating 1 existing patient for 1 year would generate \$1,439. Treating 1 new patient would generate \$1,677.

Conclusions: In a fee-for-service model, the revenue generated from increased medical visits can offset the cost of hiring a team member to support nonbillable OBOT services. (J Am Board Fam Med 2020;33:124–128.)

Opioid use disorder (OUD) is a chronic, relapsing, treatable brain disease that affects millions of Americans.¹ In recent years, the rise in incidence of

Hepatitis C, increase in emergency department and hospitalization utilization, and decrease in Americans' life expectancy have been attributed to untreated OUD.² The White House Council of Economic Advisors estimated the societal cost of opioid misuse and use disorder to be \$504 billion.³ Methadone, buprenorphine, and naltrexone are recommended by Substance Abuse and Mental Health Services Administration (SAMHSA), American Society of Addiction Medicine (ASAM), and National Institute on Drug Abuse as the standard for treatment.^{4–6} Medications for OUD have been shown to reduce fatal overdoses, improve retention in treatment, lower transmission rates of HIV infec-

tions, reduce criminal activity, and improve social functioning.² Despite the profound consequences of this disease, these medications remain highly underutilized.¹

Office-based opioid treatment (OBOT) is the provision of treatment for OUD within the general medical setting with buprenorphine or naltrexone.^{4–6} When providing OBOT, ASAM and SAMHSA recommend weekly to no-less-than monthly office visits.^{4–5} To prescribe buprenorphine, federal regulations require qualifying providers to complete additional training and receive a waiver.⁴ In 2019, only 72,696 providers are waived to prescribe buprenorphine.⁷ Less than 30% of waived providers use their waiver.⁸ Per federal law, methadone is restricted to opioid treatment programs, thus is not available in primary care.⁴

Family medicine providers are well poised to fill this treatment gap, yet many barriers to implementing OBOT in primary care exist. These include inadequately trained staff, insufficient time, inadequate office space, prescribing regulations, and lack of available mental health or psychosocial support services.⁹ To address these barriers, many successful OBOT services use a collaborative care model where a variety of disciplines provides team-based care.¹⁰ However, financial concerns may hinder the ability to implement a collaborative care model.¹¹ The purpose of this study was 2-fold. First, we sought to determine the impact of offering OBOT services on the frequency with which we saw established patients. Second, we sought to develop a financial model for hiring a team member to support nonbillable OBOT services based on the increased patient volume.

Methods

Setting

We are a community-based, family medicine residency with integrated behavioral medicine and clinical pharmacy. With 1 hub and 6 regional clinics, we serve over 33,000 patients in rural and urban communities in Appalachia. In July 2015, a faculty family medicine physician, nurse practitioner, and clinical pharmacist began providing OBOT at the main location.¹² For the first year, to gain clinical experience, we limited eligibility to established patients for at least 1 year and those maintained on a buprenorphine-containing medication. Five faculty physicians were waived to prescribe buprenor-

phine. The nurse practitioner or clinical pharmacist completed intake visits. Per the ASAM and SAMHSA recommendations, the physician saw the patient no less than monthly.^{4–5} In congruence with these guidelines, OUD is not subject to the North Carolina Medicaid annual visit limitation.¹³ Visits were billed based on time or complexity using the evaluation and management services. Beginning in June 2016, we started inductions onto buprenorphine, opened access to new patients, offered OBOT at all locations, and waived additional faculty and residents.

Data Collection

We completed a retrospective chart review from July 2015 to December 2016 to determine the number of medical visits per patient per month in the year before receiving OBOT (pre-OBOT) compared with the number of medical visits per patient per month since receiving OBOT (post-OBOT). Patients were included if they received at least 1 prescription for a buprenorphine-containing medication during the study period. Each patient's chart was reviewed from 1 year before the first prescription through the end of the study period. Information about the level of visit billed and insurance type were collected from the practice's revenue cycle management database. This study was reviewed by our local institutional review board and deemed not to be human subject research.

Data Analysis

For our first objective, the primary outcome was the average difference in medical visits per patient per month pre-OBOT to post-OBOT with a 2-tailed paired *t*-test to determine significance. Secondary outcomes were the percentage of visits coded as a Level 3, Level 4, and Level 5 and the percentage of patients with Medicaid, private insurance, or self pay. These outcomes were summarized using descriptive data. For our second objective, the primary outcome data were applied to determine the number of patients needed in OBOT to justify hiring a team member to provide nonbillable services. We used the North Carolina Medicaid Physician Fee Schedule to determine the nonfacility fee reimbursement rate.¹⁴ We accounted for a 20% reduction for cost of business, which includes central business office, provider, facilities, and staffing costs. We utilized the number of work relative value units to estimate the portion of a full-time

Table 1. Potential Annual Revenue for Providing Office-Based Opioid Treatment to New Patients

Patients, n	Level 3 Visits per Year, n	Level 4 Visits per Year, n	Level 5 Visits per Year, n	Potential Annual Revenue, \$*
25	155	467	53	41,928.28
50	311	933	105	83,856.56
75	466	1400	158	125,784.84
100	621	1867	211	167,713.12
150	932	2800	316	251,569.68
200	1242	3734	422	335,426.24

*Includes 20% reduction for cost of business.

equivalent family medicine physician required to treat the OBOT panel.^{15–16}

Results

During the study period, 23 patients received OBOT. Pre-OBOT, patients had an average of 0.32 medical visits per month (range, 0.00 to 1.17). Post-OBOT, patients had an average of 2.25 medical visits per month (range, 0.75 to 5.00). The average difference was a net increase of 1.93 medical visits per patient per month ($P < .001$). The average time post-OBOT was 4.61 months (range, 1 to 16). The total person-time of followup was 106.03 person-months. Fourteen patients were insured by Medicaid, 7 had private insurance, and 2 were self pay. Post-OBOT visits were 23.05% for Level 3, 69.14% for Level 4, and 7.81% for Level 5.

Based on these findings, we developed a financial model for new (Table 1) and current (Table 2) patients assuming all medical visits were reimbursed by North Carolina Medicaid with a 20% reduction for cost of business. Treating 1 existing patient for 1 year would generate \$1,438.61. Treating 1 new patient for 1 year would generate \$1,677.13. An OBOT panel of 100 existing patients

would require 0.7 full-time equivalents of a family medicine physician (Table 3).

Discussion

The American Medical Association Opioid Task Force calls physicians to close the treatment gap for patients with OUD.¹⁷ Family medicine practices should expand access to evidence-based, standard-of-care treatment for OUD. This financial model justifies a collaborative care model for providing the nonbillable services associated with treating OUD.

The unique needs and characteristics of a practice will undoubtedly guide which team member is most needed. Licensed clinical addiction specialists (LCAS) are utilized in primary care clinics as behavioral health specialists, care managers, and community engagement specialists.¹⁸ In Vermont's Hub-and-Spoke Model, nurses are responsible for coordination of care for patients transferring between Opioid Treatment Programs and primary care OBOT.¹⁹ Pharmacists provide education, manage medications through drug therapy management protocols, and ensure medication access.²⁰ In our institution, this financial model has created positions for 2 LCASs and 1 peer support specialist.

Table 2. Potential Annual Revenue for Providing Office-Based Opioid Treatment to Current Patients

Patients, n	Level 3 Visits per Year, n	Level 4 Visits per Year, n	Level 5 Visits per Year, n	Potential Annual Revenue, \$*
25	133	400	45	35,965.15
50	266	801	90	71,930.29
75	400	1201	136	107,895.44
100	533	1601	181	143,860.59
150	799	2402	271	215,790.88
200	1065	3203	362	287,721.17

*Includes 20% reduction for cost of business.

Table 3. Full-Time Equivalent of a Family Medicine Physician Needed for Office-Based Opioid Treatment

Patients, n	Total wRVU per Year	FTE Required
25	962.2	0.2
50	1924.4	0.3
75	2886.6	0.5
100	3848.8	0.7
150	5773.2	1.0
200	7697.6	1.3

FTE, full-time equivalent; wRVU, work relative value unit.

The responsibilities of these positions vary by role and include providing behavioral health services to patients, ensuring we meet state and federal regulations, licensing new providers, screening new patients, educating and training staff, coordinating patient care, and collaborating with outside stakeholders.

This financial model relies solely on a fee-for-service payment structure, as value-based models for OUD are not well established. In 2019, none of the quality measures recognized by the Medicare Shared Savings Program for Accountable Care Organizations address substance use disorders (SUDs).²¹ National organizations are working to expand value-based payment options for SUDs. The National Committee for Quality Assurance created initiatives for the Health care Effectiveness Data and Information Set (HEDIS) to improve follow up after an SUD-related emergency department visit.²² HEDIS implemented the Initiation and Engagement of Alcohol and Other Drug Dependence Treatment, which proposes that treatment should be started within 14 days of diagnosis and engagement with 2 or more additional services should occur within 30 days of the initial visit.²² The National Quality Forum has implemented a measure for the continuity of pharmacotherapy for OUD for 180 days for hospitals providing OBOT services in the outpatient setting.²³ The Centers for Disease Control and Prevention developed clinical quality improvement measures ensuring patients with OUD are referred to or prescribed medications for OUD.²⁴

Limitations

There are limitations to this financial model that one must consider before implementation. This financial model assumes the clinic has the capacity to accommodate the projected increase in patient

volume. Furthermore, the financial model did not account for any direct billing opportunities afforded to the new team member, which could aid in financially sustaining the position. In addition, the financial model does not account for reimbursement from private insurance companies, which is often higher than Medicaid reimbursement; therefore, this may be a conservative estimate of revenue. For the new patient model, we did not account for the 1 time initial new patient visit as it is reimbursed only slightly higher than the established patient visit at the same level.¹⁴

Conclusions

Family medicine practices use the revenue generated from increased medical visits to support collaborative care models to provide nonbillable services related to OBOT.
