

ORIGINAL RESEARCH

Patient Perceptions of Video Visits in a Fee-for-Service Model

Sirisha Moban, MD, Wilson Lin, MS, Francis Reyes Orozco, Jehni Robinson, MD, and Anjali Mahoney, MD

Introduction: We studied perceptions of patients who receive telemedicine services in the fee-for-service setting of an academic medical center's family medicine department. To the best of our knowledge, this study is the first to investigate patient sentiments on both experiential and financial aspects of telemedicine primary care with copayment collection.

Methods: A 53-question cross-sectional digital survey was delivered to patients' e-mail addresses after their telemedicine visit. We tabulated summary statistics and performed 2-sample *t*-tests to compare survey responses across groups.

Results: Of 3,414 potential respondents, 903 responded, corresponding to a 26.7% effective response rate; 797 completed surveys were analyzed. Of these, 91% described their video visit experience as more convenient than office-based care, 74% reported shorter wait times, 87% felt confident about protection of privacy, 29% perceived copayments to be unreasonable, and 91% are willing to use telemedicine again.

Discussion: Our findings suggest that telemedicine is a viable alternative to in-person visits and that most patients find a copayment reasonable. The findings suggest that telemedicine offers convenience and consistency with continuity and corroborate previous studies investigating telemedicine viewpoints. Payers should consider copayment in detail when designing telehealth benefits to ensure they do not become a barrier in seeking care. (J Am Board Fam Med 2022;35:497–506.)

Introduction

Synchronous or live telemedicine video visits have been implemented in various health care settings¹ and have rapidly scaled up^{2–5} due to COVID-19. Before the pandemic, strict reimbursement policies resulted in limited use of these services. Since the current public health crisis, legislation under the

CARES Act⁶ has enabled more payors to reimburse for telemedicine services. Our study examines patient perceptions of telemedicine visits, with specific regard to experience and copayment, in the primary care setting of an academic medical center located in Los Angeles, California.

While previous research reveals that video visits garner positive impressions from patients and providers in a variety of specialties,^{7–12} the literature on patient perceptions of telemedicine in primary care,^{13–16} as well as provider perceptions of telemedicine in primary care,^{17,18} is scarce.¹⁹ Several studies support these positive experiences but are limited to instances when telemedicine is provided at no cost and/or to established patients only. A study performed at the Massachusetts General Hospital,⁸ for example, appraises the value between telemedicine and office-based visits when telemedicine is provided free of charge. Another study considers the video visit experience of patients from the National Health Service of

Scotland,¹⁴ where beneficiaries are offered “free care, based on need and funded by general taxation.” Such studies may not be applicable in the fee-for-service model, where copayment or other costs may be required.

With the pandemic, our study investigates the perceptions of new and established patients who have been offered synchronous telemedicine services, regardless of insurance carrier. Some studies^{20–22} evaluate the financial view of clinical care in the emergency department and urgent care settings; to the best of our knowledge, we believe we are one of the first studies to focus on both the experiential and financial views of telemedicine primary care services when patients may need to provide a copayment.

Methods

Study Design and Setting

Our study describes completed survey results from patients who completed a telemedicine video visit between April and December 2020.

University of Southern California Telemedicine Program

The Department of Family Medicine launched telemedicine services in October 2019 with 1 provider in 1 clinic location. Given physical distancing recommendations and health policy waivers prompted by the COVID-19 pandemic, these services expanded to more than 20 providers across 4 clinical sites. A workflow was designed to replicate the face-to-face office visit experience, which allowed clerical staff to collect copayments efficiently.

Once a telemedicine visit was scheduled, a personalized link was sent to the patient’s e-mail. At the time of the visit, the patient used the link to log into the telemedicine platform, which then initiated the encounter. The patient received and signed an electronic consent form that enabled the delivery of health care services. Like face-to-face office visits, the patient was greeted by clerical staff and a copayment was collected as pertinent to the patient’s health insurance. Next, the patient connected to the medical assistant and eventually to the provider, who completed the virtual visit. Based on the level of complexity or time spent with the patient, an evaluation and management charge was submitted and billed to insurance.

Telemedicine Video Visit Survey

Study participants were identified through the electronic medical record. A personalized link generated through Qualtrics was sent to the participant’s e-mail address with an invitation to participate in a 53-item electronic survey following the telemedicine visit. Participants who did not respond to the initial e-mail notification were sent e-mail reminders via Qualtrics on days 7, 14, 21, and 28.

The cross-sectional digital survey queried participants on demographics like age, sex, race/ethnicity, marital status, education, employment status, and income. Patient experience and satisfaction questions were developed by the Family Medicine faculty, along with insights from review of the literature. In particular, the National Quality Forum’s report for quality measures in telehealth guided development of questions²³ related to quality of care received, satisfaction, technology, communication, and time with the provider, transportation, and copayment. An earlier version of the survey was piloted during the department’s pilot of telemedicine services, from October 2019 to March 2020.

The study was reviewed and approved by the University of Southern California Institutional Review Board as an expedited study (IRB ID: HS-19-00678).

Analyses

Survey Sampling

In all, 903 participants completed the survey. Respondents who declined to participate or provided feedback that was not consistent with that of Family Medicine telemedicine practices (eg, a phone call took place, or the provider was not from Family Medicine) were excluded from the analyzed sample.

Data Coding

Respondents who entered values corresponding to an unreasonable age, for example, 775, had their age cleared. Free text responses with “other” were reviewed and recoded into default responses when possible. Free text entries noting a copayment to be unreasonable were coded under assigned themes.

Distance from Clinic

In determining differences between typical and actual distance from the patient and the clinic, each patient’s zip code was cross-referenced with the

provider's clinic zip code using the NBER Zip Code Distance Database.²⁴

Statistical Analysis

The data are described as absolute numbers and percent frequency of occurrence. We perform a statistical analysis to compare the actual and typical distance from the clinic using paired *t*-tests and subgroup analyses between reported demographics using 2-sample *t*-tests. Stata 15 and the usespss package was used to process the Qualtrics data.

Results

3414 potential respondents received the survey, of which 3377 were successfully contacted. In all, 903 respondents replied to the study, corresponding to a 26.7% effective response rate. Of these, 73 declined to participate, and 33 provided feedback inconsistent with Family Medicine telemedicine practices. A total of 797 surveys were analyzed and represent patient experiences from 25 Family Medicine physicians and advanced practice providers.

Primary Analyses

Demographics and Baseline Medical

Appointment Visits

Baseline demographics and medical appointment information of study respondents are reported in Table 1 and Table 2. Survey respondents were of similar backgrounds to commercial telehealth users.¹ Fifty-four percent (427/797) of respondents reported being first-time telehealth users.

Transportation

Survey respondents used their personal vehicle most frequently to travel to their in-person visits (84%, 666/797) and most frequently mentioned that they were 4 to 10 miles away (51%, 480/797) or 16 to 30 minutes away (39%, 308/797) from their provider's clinic.

Distance

Table 2 shows the typical and actual distance to the indicated provider's clinical site, as measured by zip code. Using a paired 2-tailed *t*-test, we found statistical significance between the 2 metrics when looking at respondents whose typical distances were less than 200 miles ($n = 721$; typical: mean 11.2 miles, SD 16.7 miles; actual: mean 14.1 miles, SD 39.1 miles). The difference between the 2 values

suggests that respondents are located farther away from their medical home during the pandemic, possibly due to a permanent or temporary move of place of residence.

Logistics

While 82% (650/797) of respondents spent less than 15 minutes coordinating their visit, 7% (58/797) reported coordination times lasting longer than 30 minutes. Most respondents conducted their visits from home (91%, 724/797) or workplace (6%, 51/797). Other indicated locations included their vehicle and the homes of other family members. Respondents typically used a laptop (48%, 379/797) or smartphone (34%, 268/797) for their visit; desktops (11%, 87/797) and tablets (7%, 59/797) were less used.

Comparisons to Office Visits

Figure 1 reports survey respondents' perceptions of video visits compared with office visits.

Ninety-one percent (727/797) of respondents described their telemedicine video visit as somewhat or very convenient. Seventy-four percent (592/797) reported somewhat or much shorter wait times, and 72% (572/797) reported a shorter time for coordinating and taking part in their visit.

Provider Experience

Survey respondents revealed positive interactions with providers, and nearly all respondents agreed that they could see (93%, 743/797) and hear (96%, 762/797) their provider clearly. An overwhelming majority felt that the provider spent enough time with them (96%, 767/797) and had enough time to discuss their issues (93%, 745/797). When asked about communication, 97% (775/797, 773/797) found that their clinician explained things in a way that was easy to understand and that they were carefully listened to. Most felt confident about the care plan provided (89%, 710/797).

Privacy

While 87% (693/797) of respondents felt confident that their privacy was protected during their video visit, 70% (558/797) were comfortable in discussing their concerns, and 26% (205/797) felt uncomfortable to discuss their concerns via this modality.

Outlook

Eighty-one percent (653/797) of respondents strongly agreed that a telemedicine visit was a good

Abbreviations: SD, standard deviation.

option to see their doctor due to COVID-19 concerns. More than 90% of respondents (719/797) were satisfied or very satisfied with their visit, with 91% (723/797) expressing that they would be fairly (19%, 158/797) or completely (71%, 565/797) willing to use telemedicine again. Figure 2 shows preferred times for video visits to be 9 AM–3 PM, and on weekdays more than weekends generally.

Secondary Analyses

To understand whether there was heterogeneity in survey responses, we ran 2-sample *t*-tests on the 5-point Likert scale questions by demographics (above median income—\$75,000 or above, some college education, gender, elderly—above 65 years old, patient status with Family Medicine, new user of telehealth). We found significant variation in responses for the following areas, as summarized in Table 3:

1. Respondents of higher household income ($P < 0.001$) and new users of telehealth ($P < 0.001$) were more willing to be seen by other Family

Medicine providers (not their regularly assigned provider for a returning patient, or not the assigned provider for the visit of a new patient).

2. Respondents who were new users of telehealth were more willing to use video visits again in the future ($P = 0.0303$).
3. Respondents with some college education felt less confident about their privacy being protected ($P = 0.0415$), while those with higher incomes and the elderly felt more confident about their privacy being protected ($P = 0.0139$, $P = 0.0151$).
4. Elderly respondents felt more satisfied about their video visits ($P = 0.0123$) but also felt less strongly about telehealth taking less time to coordinate and take part in an office visit ($P < 0.001$).

Copayment

Twenty-nine percent (235/797) of respondents indicated that a copayment was unreasonable. Of

Figure 1. Video visits rated better than office visits in 3 domains (n = 797).

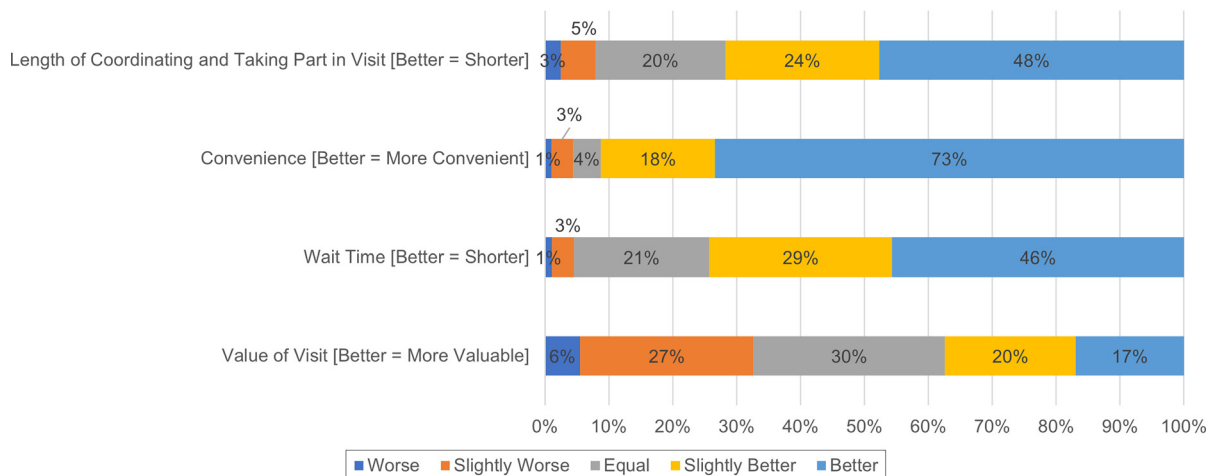

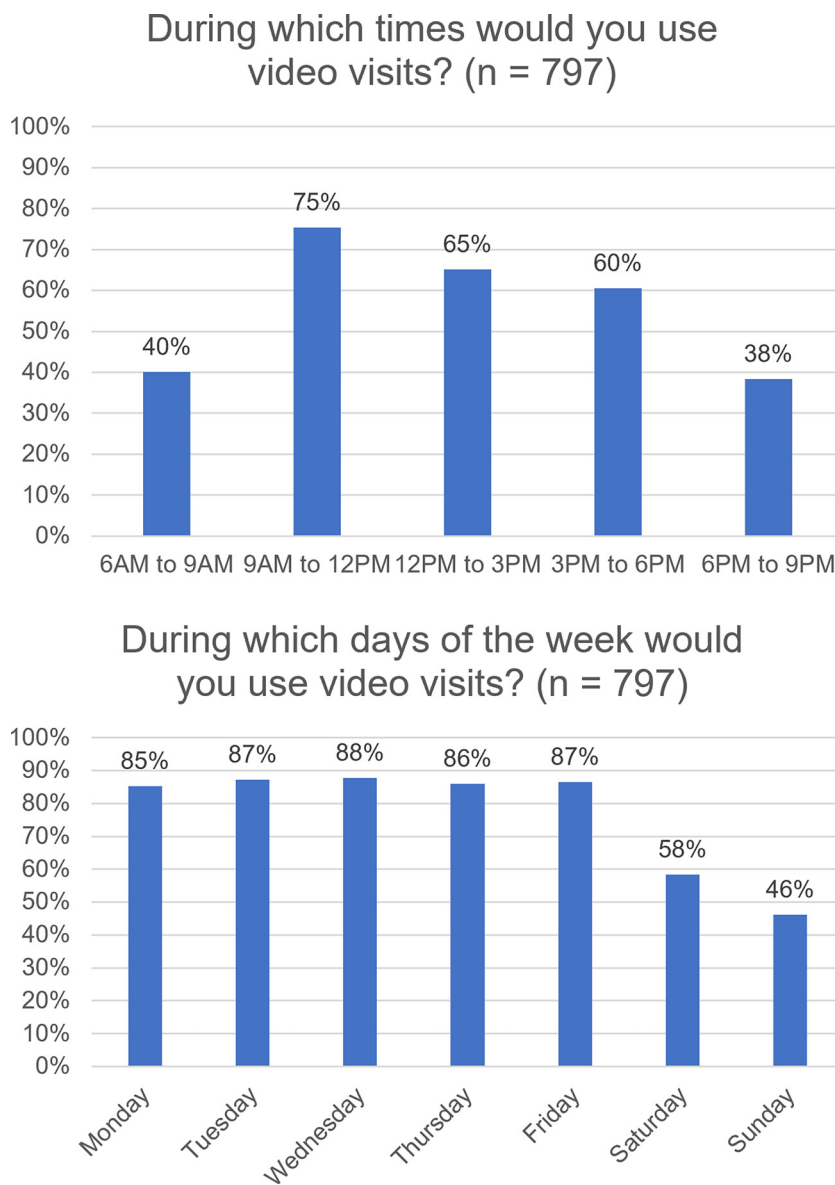

Figure 2. Times and days of the week in which patients were willing to use video visits (multiple selections allowed).

these responses, 25% (59/235) were EPO (exclusive provider organization) carriers, 47% (111/235) were PPO (preferred provider organization) carriers, 23% (54/235) Medicare/Medi-Cal beneficiaries, and 5% (11/235) had other insurance or had no insurance. Using 2-sample *t*-tests, we find that patients with some college education (73% average with vs 51% average without, $P = .0000$), with above median household income (78% average if above vs 60% if below, $P = .0000$), and who are existing Family Medicine patients (73% average if existing, 66% average if new, $P = .0317$) are more likely to find a copayment reasonable. Willingness to see other Family Medicine physicians ($\rho = -0.2575$) and satisfaction with video visits

($\rho = -0.2077$) had the strongest correlations with willingness to submit a copayment.

A lack of a physical examination (34%, 79/235) was the most common explanation for the sentiment. Some patients felt strongly about this: "They cannot really check your vitals. That is mainly the point of visiting a doctor." "I cannot have my doctor check for concerns that need to be assessed through looking or feeling," "touch and smell are not involved." A perceived sense of lessened care was noted in 2 primary aspects: (1) respondents felt the health system/provider saved resources/overhead costs by not needing to visit a clinic space or that providers conducted the visit from their own

Table 3. Secondary Analyses (Means of Responses Provided by Demographic Group)

How willing would you be using the TeleCARE platform to be seen by other physicians at University of Southern California Family Medicine? (1 = completely willing...5 = not at all willing)			
Income	<\$75000 (n = 459)	>=\$75000 (n = 274)	<i>P</i> value
	1.861	1.588	< 0.001

	4.554	4.356	0.0415
Income	<\$75000 (n = 459)	>=\$75000 (n = 274)	<i>P</i> value
	4.296	4.458	0.0139
Age	<65 (n = 626)	65+ (n = 162)	<i>P</i> value
	4.343	4.531	0.0151
Overall, how satisfied are you with your telehealth visit? (1 = very satisfied...5 = very dissatisfied)			
Age	<65 (n = 626)	65+ (n = 162)	<i>P</i> value
	1.597	1.389	0.0123
Compared to an office visit, how long did it take for you to coordinate and participate in your TeleCARE video visit? (1 = much shorter than an office visit...5 = much longer than an office visit)			
Age	<65 (n = 626)	65+ (n = 162)	<i>P</i> value
	1.823	2.204	< 0.001

home (12%, 28/235), and (2) the reason for a video visit was straightforward (ie, a prescription refill, bloodwork) or took less time as compared with an in-person visit (25%, 59/235). Relevant financial concerns (14%, 34/235) consisted of (1) those respondents not needing to submit a copayment (9%, 20/235), (2) preference to see a reduced copay versus in person (7%, 17/235), or (3) combination of other reasons. Technical concerns and COVID-19 were given as justification in 13 and 8 responses, respectively.

Other Feedback

Additional free text commentary of video visit experiences is described here. Some respondents were especially satisfied with their experience (“It was amazing and long overdue,” “I have more health care appointments than most people and have been DELIGHTED by telecare system. So much less

commute time!”) and expressed continued use of the service postpandemic (“Please continue telehealth even after covid”). While some commented on the strengths of the modality (“I do have anxiety about seeing the doctor, so this was good for my comfort level”), while other respondents described difficulties of interacting through video (“hard to explain myself through a computer,” “In addition, I’ve back problems, and sitting waiting an hour for the visit to begin can aggravate it”). Seven patients were resistant toward telehealth (“During COVID 19 I can understand its need, but when conditions return to normal, I am not interested in this process”).

Discussion

Conducted in the family medicine setting of an academic medical institution, where cost for services is rendered, our study finds that survey respondents

perceive telemedicine services favorably, with 71% of respondents perceiving a copayment to be reasonable. However, 29% of respondents felt that a copayment was unreasonable, listing a lack of a physical examination and personal financial concerns as reasons for this sentiment. Despite these observations, we find that respondents value telemedicine visits as equal to or greater than traditional office visits and describe positive experiences with efficiency, convenience, decreased wait time to see a provider, and time in coordinating and participating in care. This illustrates that telemedicine is useful in increasing access to primary care and suggests that video visits are an acceptable medium for care, as an overwhelming number of respondents (91%) were fairly or completely willing to use telemedicine video visits again in the future. Our findings contribute to the nascent literature on primary care telemedicine practices,^{13,16,19,25,26} telemedicine video visits,^{7,8,18,27} and patients' copayment perceptions.^{20–22}

To the best of our knowledge, this study is one of the first to explore patient perceptions of telemedicine services in primary care when patients may need to pay for services, unlike previous studies where visits were free of charge.⁸ This study took place during the COVID-19 pandemic, a time when patients were offered telemedicine as an alternative to in-person visits. Under these circumstances, the study collected responses from a multitude of providers' patients. This differs from other studies where respondents were either self-selected or selected by their provider to participate in a telemedicine visit.^{8,10} Given this population sample, we believe our study to be more externally valid.

One limitation of the study is that we received a relatively low response rate. Incidentally, the low response rate of the study may have introduced bias, as possibly noted by the overrepresentation of specific demographic groups (e.g. female, higher educational/income backgrounds). In addition, our study was partially conducted during the shelter-at-home orders put in place by the state of California, which likely affected responses on where patients were conducting their visits from. In addition, this might have caused providers to be considered as front-line workers, possibly leading to higher satisfaction rate in responses. Respondents were neither queried on the amount or existence of a copayment nor other cost related to care. Conversely, about half of respondents were first-time users of telehealth, which is a significant increase from prior studies.²⁷ Similarly, the

percentage of respondents who expressed high willingness to use telemedicine in the future may be upward biased, as the study was conducted during a period when patients may have especially feared having in-person visits. Lastly, as our study focuses on those who were able to conduct a telemedicine video visit, our study does not capture the perceptions of patients who do not have access to telemedicine video visits, such as those without Internet access, those who do not have access to a computer or smartphone, or the very elderly who may be unable to operate technologies by themselves, among other groups. Given these limitations, we suggest that generalizing these results should be done with careful consideration, although our results may be applicable to other academic medical centers as well.

The findings of this study suggest that telemedicine video visits continue to be a promising modality for accessing primary care. Moreover, the findings suggest that payors should consider copayment in detail when designing telehealth benefits to ensure such copayments do not become a barrier in seeking care. That is, payors may be able to affect telemedicine use by setting the copayment rates and reimbursement rates for telemedicine visits accordingly. For example, payors could discourage telemedicine use by setting very high copayments for patients. They also underline the need to establish best practices for patients and providers that could determine the use of telehealth in the future. Our study suggests that further inquiry is needed to determine the significance of the Internet as a household utility and technology as determinants of health care access. Additional studies may consider the factors that contribute to telemedicine use to ensure that telemedicine does not widen the health disparities in our communities.
